

PYRANONE COMPOUNDS USEFUL TO TREAT RETROVIRAL INFECTIONS

insert B1

The present invention relates to compounds useful for inhibiting a retrovirus in a human cell infected with said retrovirus. More particularly, the present invention provides pyran-2-ones, 5,6-dihydropyran-2-ones, 4-hydroxy-benzopyran-2-ones, 4-hydroxy-cycloalkyl[b]pyran-2-ones, and derivatives thereof as HIV-proteinase inhibitors.

BACKGROUND OF THE INVENTION

During the past decade, acquired immunodeficiency syndrome (AIDS) has progressed from having the status of a medical curiosity afflicting only a small number of individuals to a problem of major proportions, both medically and economically. John Saunders and Richard Storer, "New Developments in RT Inhibitors," DN&P 5(3), April 1992, pages 153-169. WHO figures reveal that more than 360,000 cases of AIDS have been reported worldwide, including nearly 175,000 cases in the U.S.A. Of these, approximately 100,000 worldwide (50,000 in the U.S.A.) were reported in the preceding 12-month period. In the U.S.A., the number of seropositive individuals is thought to be approximately two million, and estimates suggest that 5-10 million people worldwide may be seropositive. Saunders and Storer, page 153.

Since the first description of the malady in the early part of this decade, acquired immunodeficiency disease syndrome (AIDS) and its devastating consequences have been subjects of continuous and intense coverage in both the lay and scientific press. Indeed, an edition of Scientific American was entirely devoted to AIDS (Scientific American 289, #4 (1988)), and the literature on the disease and the virus is already so vast as to defy thorough citation.

On March 20, 1987, the FDA approved the use of the compound, zidovudine (AZT), to treat AIDS patients with a recent initial episode of pneumocystis carinii pneumonia, AIDS patients with conditions other than pneumocystis carinii pneumonia or patients infected with the virus with an absolute CD4 lymphocyte count of less than $200/\text{mm}^3$ in the peripheral blood. AZT is a known inhibitor of viral reverse transcriptase, an enzyme necessary for human immunodeficiency virus replication. U.S. Patent 4,724,232 claims a method of treating humans having acquired immunodeficiency syndrome utilizing 3'-azido-3'-deoxy-thymidine (azidothymidine, AZT).

Following the discovery of the anti-HIV activity of AZT, much effort has been focused on a wide variety of other dideoxynucleoside analogues in the search for

superior agents. In the case of the 2'.3'-dideoxy series, ddC and ddI have shown potent activity against HIV *in vitro* and have been evaluated in clinical trials. Saunders and Storer, page 160. The compound ddC is currently being developed by Hoffman-La Roche Co. as a potential anti-AIDS drug. Its limiting toxicity in humans is peripheral neuropathy which is reversible at low doses. Raymond R. Schinazi, Jan R. Mead and Paul M. Feorino, "Insights Into HIV Chemotherapy," AIDS Research and Human Retroviruses, Vol. 8, Number 6, 1992, pages 963-990. It has been approved by the FDA for AIDS therapy in combination with AZT. The compound ddI has also been evaluated in clinical trials. Its limiting toxicities are peripheral neuropathy and pancreatitis. It has also been shown to stimulate hepatic glycolysis leading to irreversible liver damage. Schinazi, Mead and Feorino, page 966. It has recently been approved by the FDA for the treatment of HIV-1 infections in adults and pediatric patients who are intolerant to or whose health has significantly deteriorated while on AZT treatment. Schinazi, Mead and Feorino, page 966.

Among these approved drugs, AZT is currently the only drug that has been shown to decrease the mortality and frequency of opportunistic infections associated with AIDS. Schinazi, Mead and Feorino, page 963.

Human immunodeficiency virus (HIV) has long been recognized as the causative agent in AIDS, although a minority opinion to the contrary has been expressed (e.g., P. Duesberg, Proc. Natl. Acad. Sci., USA, 86:755-764 (1989)). Sequence analysis of the complete genomes from several infective and non-infective HIV-isolates has shed considerable light on the make-up of the virus and the types of molecules that are essential for its replication and maturation to an infective species. The HIV protease is essential for the processing of the viral gag and gag-pol polypeptides into mature virion proteins. L. Ratner, et al., Nature, 313:277-284 (1985); L.H. Pearl and W.R. Taylor, Nature, 329:351 (1987). HIV exhibits the same gag/pol/env organization seen in other retroviruses. L. Ratner, et al., above; S. Wain-Hobson, et al., Cell, 40:9-17 (1985); R. Sanchez-Pescador, et al., Science, 227:484-492 (1985); and M.A. Muesing, et al., Nature, 313:450-458 (1985).

Reverse transcriptase (RT) is an enzyme unique to retroviruses that catalyzes the conversion of viral RNA into double stranded DNA. Blockage at any point during the transcription process, by AZT or any other aberrant deoxynucleoside triphosphate incapable of elongation, should have dramatic consequences relative to viral replication. Much work on the RT target is in progress based, in large measure, upon the fact that nucleosides like AZT are easily delivered to cells.

However, the inefficiency of phosphorylation steps to the triphosphate, and the lack of specificity and consequent toxicity, constitute major drawbacks to use of AZT and similar nucleosides having a blocked, or missing, 3'hydroxyl group.

The T4 cell receptor for HIV, the so-called CD4 molecule, has also been
5 targeted as an intervention point in AIDS therapy. R.A. Fisher, et al., *Nature*, 331:76-78 (1988); R.E. Hussey, et al., *Nature*, 331:78-81 (1988); and K.C. Deen, et al., *Nature*, 331:82-84 (1988). The exterior portion of this transmembrane protein, a molecule of 371 amino acids (sCD4) has been expressed in Chinese hamster ovary (CHO) cells and Genentech (D.H. Smith, et al., *Science*, 238:1704-1707 (1987)) has
10 had a product in clinical trials since the fall of 1987. CD4 has been shown to have a narrow spectrum of activity against wild-type virus and so far has failed to control HIV infection in humans. Schinazi, Mead and Feorino, page 963. The idea behind CD4 based therapy is that the molecules can neutralize HIV by interfering with viral attachment to T4, and other cells which express CD4 on their surfaces. A
15 variant on this theme is to attach cell toxins to CD4 for specific binding and delivery to infected cells which display glycoprotein gp-120 on their surfaces. M.A. Till, et al., *Science*, 242:1166-1168 (1988); and V.K. Chaudhary, et al., *Nature*, 335:369-372 (1988).

Another therapeutic target in AIDS involves inhibition of the viral protease
20 (or proteinase) that is essential for processing HIV-fusion polypeptide precursors. In HIV and several other retroviruses, the proteolytic maturation of the gag and gag/pol fusion polypeptides (a process indispensable for generation of infective viral particles) has been shown to be mediated by a protease that is, itself, encoded by the pol region of the viral genome. Y. Yoshinaka, et al., *Proc. Natl. Acad. Sci. USA*,
25 82:1618-1622 (1985); Y. Yoshinaka, et al., *J. Virol.*, 55:870-873 (1985); Y. Yoshinaka, et al., *J. Virol.*, 57:826-832 (1986); and K. von der Helm, *Proc. Natl. Acad. Sci., USA*, 74:911-915 (1977). Inhibition of the protease has been shown to inhibit the processing of the HIV p55 in mammalian cell and HIV replication in T lymphocytes. T.J. McQuade, et al., *Science*, 247:454 (1990).

30 The protease (or proteinase), consisting of only 99 amino acids, is among the smallest enzymes known, and its demonstrated homology to aspartyl proteases such as pepsin and renin (L.H. Pearl and W.R. Taylor, *Nature*, 329:351-354 (1987); and I. Katoh, et al., *Nature*, 329:654-656 (1987)), led to inferences regarding the three-dimensional structure and mechanism of the enzyme (L.H. Pearl and W.R. Taylor,
35 above) that have since been borne out experimentally. Active HIV protease has been expressed in bacteria (see, e.g., P.L. Darke, et al., *J. Biol. Chem.*, 264:2307-2312

(1989)) and chemically synthesized (J. Schneider and S.B. Kent, Cell, 54:363-368 (1988); and R.F. Nutt, et al., Proc. Natl. Acad. Sci., USA, 85:7129-7133 (1988)). Site directed mutagenesis (P.L. Darke, et al., above); and N.E. Kohl, et al., Proc. Natl. Acad. Sci., USA, 85:4686-4690 (1988)) and pepstatin inhibition (P.L. Darke, et al., J. Biol. Chem., 264:2307-2312 (1989); S. Seelmeier, et al., Proc. Natl. Acad. Sci., USA, 85:6612-6616 (1988); C.-Z. Giam and I. Borsos, J. Biol. Chem., 263:14617-14720 (1988); and J. Hansen, et al., EMBO J., 7:1785-1791 (1988)) have provided evidence for HIV protease's mechanistic function as an aspartyl protease. A study has demonstrated that the protease cleaves at the sites expected in peptides modeled after the regions actually cleaved by the enzyme in the gag and pol precursor proteins during viral maturation. P.L. Darke, et al., Biochem. Biophys. Res. Commun., 156:297-303 (1988). X-ray crystallographic analysis of the HIV-protease (M.A. Navia, et al., Nature, 337:615-620 (1989)) and a related retroviral enzyme from Rous sarcoma virus (M. Miller, et al., Nature, 337:576-579 (1989)) reveal an active site in the protease dimer that is identical to that seen in other aspartyl proteases, thus supporting the supposition (L.H. Pearl and W.R. Taylor, above) that the HIV enzyme is active as a dimer. See also Joseph A. Martin, "Recent Advances in the Design of HIV Proteinase Inhibitors," Antiviral Research, 17 (1992) 265-278.

To date, the scientific search for a fully effective and safe means of inhibiting retroviruses in a human hosting such a virus, and thereby effectively treating diseases caused by such a virus, such as acquired immunodeficiency syndrome (AIDS), continues.

The compounds of the present invention are named according to the IUPAC or CAS nomenclature system.

The carbon atoms content of various hydrocarbon-containing moieties is indicated by a prefix designating the minimum and maximum number of carbon atoms in the moiety, i.e., the prefix $\text{C}_i\text{-C}_j$ indicates a moiety of the integer "i" to the integer "j" carbon atoms, inclusive. Thus, for example, $\text{C}_1\text{-C}_3$ alkyl refers to alkyl of one to three carbon atoms, inclusive, or methyl, ethyl, propyl, and isopropyl, straight and branched forms thereof.

Also, the carbon atom content of various hydrocarbon-containing moieties of the present invention is indicated by a subscripted integer representing the number of carbon and hydrogen atoms in the moiety, e.g., " C_nH_{2n} " indicates a moiety of the integer "n" carbon atoms, inclusive, and the integer "2n" hydrogen atoms, inclusive. Thus, for example, " C_nH_{2n} " wherein n is one to three carbon atoms, inclusive, and two to six hydrogen atoms, inclusive, or methyl, ethyl, propyl and isopropyl, and all isomeric, straight and branched forms thereof.

Examples of alkyl of one to nine carbon atoms, inclusive, are methyl, ethyl, propyl, butyl, pentyl, hexyl, heptyl, octyl, and nonyl, and all isomeric forms thereof and straight and branched forms thereof.

Examples of alkenyl of one to five carbon atoms, inclusive, are ethenyl, propenyl, butenyl, pentenyl, all isomeric forms thereof, and straight and branched forms thereof.

By "halo" is meant the typical halogen atoms, such as fluorine, chlorine, bromine, and iodine.

The compounds of formula I and II of the present invention inhibit retroviral proteinases and thus inhibit the replication of the virus. They are useful for treating patients infected with human immunodeficiency virus (HIV) which results in acquired immunodeficiency syndrome (AIDS) and related diseases.

More particularly, the compounds of the present invention are useful as novel human retroviral protease inhibitors. Therefore, the compounds inhibit retroviral proteases and thus inhibit the replication of the virus. They are useful for treating human patients infected with a human retrovirus, such as human immunodeficiency virus (strains of HIV-1 or HIV-2) or human T-cell leukemia viruses (HTLV-I or HTLV-II) which results in acquired immunodeficiency syndrome (AIDS) and/or related diseases.

The capsid and replicative enzymes (i.e. protease, reverse transcriptase,

integrase) of retroviruses are translated from the viral gag and pol genes as polyproteins that are further processed by the viral protease (PR) to the mature proteins found in the viral capsid and necessary for viral functions and replication. If the PR is absent or nonfunctional, the virus cannot replicate. The retroviral PR, such as HIV-1 PR, has been found to be an aspartic protease with active site characteristics similar to those exhibited by the more complex aspartic protease, renin.

The term human retrovirus (HRV) includes human immunodeficiency virus type I, human immunodeficiency virus type II, or strains thereof, as well as human T cell leukemia virus 1 and 2 (HTLV-1 and HTLV-2) or strains apparent to one skilled in the art, which belong to the same or related viral families and which create similar physiological effects in humans as various human retroviruses.

Patients to be treated would be those individuals: 1) infected with one or more strains of a human retrovirus as determined by the presence of either measurable viral antibody or antigen in the serum and 2) in the case of HIV, having either an asymptomatic HIV infection or a symptomatic AIDS defining infection such as i) disseminated histoplasmosis, ii) isopsoriasis, iii) bronchial and pulmonary candidiasis including pneumocystic pneumonia iv) non-Hodgkin's lymphoma or v) Kaposi's sarcoma and being less than sixty years old; or having an absolute CD4+ lymphocyte count of less than $500/\text{mm}^3$ in the peripheral blood. Treatment would consist of maintaining an inhibitory level of the compound used according to this invention in the patient at all times and would continue until the occurrence of a second symptomatic AIDS defining infection indicates alternate therapy is needed.

More specifically, an example of one such human retrovirus is the human immunodeficiency virus (HIV, also known as HTLV-III or LAV) which has been recognized as the causative agent in human acquired immunodeficiency syndrome (AIDS), P. Duesberg, Proc. Natl. Acad. Sci. USA, 86:755 (1989). HIV contains a retro viral encoded protease, HIV-I protease, that cleaves the fusion polypeptides into the functional proteins of the mature viral particle, E.P. Lillehoj, et al., J. Virology, 62:3053 (1988); C. Debuck, et al., Proc. Natl. Acad. Sci., 84:8903 (1987). This enzyme, HIV-I protease, has been classified as an aspartyl protease and has a demonstrated homology to other aspartyl proteases such as renin, L.H. Pearl, et al., Nature 329:351 (1987); I. Katoh, et al., Nature 329:654 (1987). Inhibition of HIV-I protease blocks the replication of HIV and thus is useful in the treatment of human AIDS, E.D. Clerq, J. Med. Chem. 29:1561 (1986). Inhibitors of HIV-I protease are useful in the treatment of HIV-infected individuals who are asymptomatic or

symptomatic of AIDS.

Pepstatin A, a general inhibitor of aspartyl proteases, has been disclosed as an inhibitor of HIV-I protease, S. Seelmeier, et al., Proc. Natl. Acad. Sci. USA, 85:6612 (1986). Other substrate derived inhibitors containing reduced bond

5 isosteres or statine at the scissle position have also been disclosed, M.L. Moore, et al., Biochem. Biophys. Res. Commun. 159:420 (1989); S. Billich, et al., J. Biol. Chem. 263:17905 (1988); Sandoz, D.E. 3812-576-A.

Thus, the compounds of the present invention are useful for treating diseases caused by retroviruses, such as human acquired immunodeficiency disease syndrome
10 (AIDS).

The compounds are also useful for treating non-human animals infected with a retrovirus, such as cats infected with feline leukemia virus. Other viruses that infect cats include, for example, feline infectious peritonitis virus, calicivirus, rabies virus, feline immunodeficiency virus, feline parvovirus (panleukopenia virus), and
15 feline chlamydia. Exact dosages, forms and modes of administration of the compounds of the present invention to non-human animals would be apparent to one of ordinary skill in the art, such as a veterinarian.

The compounds of formula I and II of the present invention are prepared as described in the Charts, Preparations and Examples below, or are prepared by
20 methods analogous thereto, which are readily known and available to one of ordinary skill in the art of organic synthesis.

CHART A

Nitration of the cyclopropylphenyl ketone of formula A-1, which is commercially available, with fuming nitric acid at -40 °C produces a ca. 2:1 mixture
25 of isomers. The desired *m*-nitro compound of formula A-2 is easily separated from the crude mixture by recrystallization from methanol. Catalytic hydrogenation of the cyclopropyl-(3-nitrophenyl)methanone of formula A-2 with 10% platinum on carbon in methanol gives the aniline of formula A-3. The aniline is then coupled with benzenesulfonyl chloride using pyridine in methylene chloride to give the
30 sulfonamide derivative of formula A-4. Reduction of the ketone with sodium borohydride in tetrahydrofuran and ethanol then produces the carbinol of formula A-5.

The dianion of the cyclooctylpyranone of formula A-6, prepared as described in Chart B, is formed using lithium diisopropyl amide in tetrahydrofuran at 0 °C,
35 and then alkylated with iodopropane to give the 10-propyl-cyclooctylpyranone of formula A-7. The cyclooctylpyranone of formula A-7 and the carbinol of the formula

A-5 are then coupled using *p*-toluenesulfonic acid in methylene chloride to give the sulfonamide derivative of formula A-8.

CHART B

The commercially available amine of the formula B-1 is protected using
5 benzyl chloroformate and sodium bicarbonate in THF/water solution to give the compound of formula B-2. The aldehyde of formula B-2 is then reacted with a Grignard reagent to give the secondary alcohol of formula B-3, wherein, e.g., R₁ is isobutyl. The known cyclooctylpyranone of formula B-4 is prepared by acylation of the trimethylsilyl enol ether of cyclooctanone with malonyl dichloride as described in
10 R. Effenberger, T. Ziegler, K.-H. Schonwalder, T. Kesmarszky, B. Bauer Chem. Ber. 119:3394-3404 (1986). The alcohol of formula B-3 is then used to alkylate the cyclooctylpyranone of formula B-4 in refluxing toluene and *p*-toluenesulfonic acid to obtain the compound of the formula B-5, wherein, e.g., R₁ is isobutyl. At this point, the enantiomers of formula B-5 are separated using a chiral HPLC column. The
15 benzyloxy protecting group is then cleaved using 10% Pd/C in cyclohexene to give the amine of formula B-6, wherein, e.g., R₁ is isobutyl, which is reacted with aryl sulfonyl chlorides to give the compounds of the formula B-7, wherein, e.g., R₁ is isobutyl and R₂ is 1-methylimidazole.

CHART C

20 3-Bromobenzyl alcohol of formula C-1, which is commercially available, in tetrahydrofuran is treated with methyllithium, *n*-butyllithium and cyclopropanecarboxaldehyde in sequence at -78°C. The resulting solution is gradually warmed to room temperature and then heated at reflux affording the alcohol of formula C-2. The resulting alcohol, in dichloromethane, in the presence of molecular
25 sieves, is treated with 4-hydroxy-5,6,7,8,9,10-hexahydrocycloocta[b]pyran-2-one of formula C-8, prepared as described in Chart B, and *p*-toluenesulfonic acid. The solution is heated at reflux to afford the alcohol of formula C-3. CHART N

Nitration of cyclopropylphenyl ketone of formula N-1, which is commercially available, with fuming nitric acid at -40 °C produces a ca. 2:1 mixture of isomers. The desired meta-nitro compound of formula N-2 is easily separated from the crude mixture by recrystallization from methanol. Catalytic hydrogenation of cyclopropyl-(3-nitrophenyl)methanone of formula N-2 with 10% platinum on carbon in methanol at 0 °C provides the aniline of formula N-3. The product is isolated by filtration and concentration. The amino group is then protected using benzyl chloroformate and diisopropylethylamine in methylene chloride to give the ketone of formula N-4. The ketone is then reduced with sodium borohydride in 5:1 THF and ethanol to give the alcohol of formula N-5.

The compound of formula N-5 is then used to alkylate 4-hydroxy-5,6,7,8,9,10-

hexahydrocycloocta[b]pyran-2-one, which is prepared as described in R. Effenberger, T. Ziegler, K.-H. Schönzoalder, T. Kesmarsky, B. Bauer, Chem. Ber. 119:3394-3404 (1986), to give the compound of formula N-6. The preferred conditions for this alkylation reaction are *p*-toluene-sulfonic acid in refluxing methylene chloride with a Soxhlet extractor containing molecular sieves. CHART O

Treatment of the amine of formula O-1, prepared as described in Chart N, with sulfonyl chlorides and a base such as pyridine in dichloromethane gives the sulfonamides of formula O-2 wherein R₆₀ is, for example, 4-nitrophenyl. These sulfonamides are further modified by standard literature procedures as is apparent to those of ordinary skill in the art to give sulfonamides of formula O-3 wherein R₆₁ is, for example, 4-aminophenyl and other functional groups that are not readily available from readily available sulfonyl chlorides. For example, the nitro group of N-[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]-4-nitro-benzenesulfonamide is reduced by catalytic hydrogenation in ethyl acetate with palladium on carbon to give the amine in 4-amino-N-[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]-benzenesulfonamide. Also, the carboxylic acid of 3-[[[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]amino]sulfonyl]-benzoic acid is esterified with methanol and catalytic sulfuric acid to give the methyl ester in 3-[[[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]amino]sulfonyl]-benzoic acid, methyl ester. Sulfonamides of formula O-3 are also obtained from compounds of formula O-2 by further elaboration of reactive functional groups. For example, the amine of 3-amino-N-[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]-benzenesulfonamide is reacted with benzoyl chloride and a base such as pyridine to give the benzamide in N-[3-[[[3-[cyclopropyl(5,6,7,8,9,10-hexahydro-4-hydroxy-2-oxo-2H-cycloocta[b]pyran-3-yl)methyl]phenyl]amino]sulfonyl]henyl]-benzamide. Using commonly available sulfonyl chlorides, additional compounds of the present invention of formula II, wherein R₁₀ and R₂₀ is the moiety of formula IV, are prepared.

The sulfonyl chlorides used to make the compounds of the present invention are readily prepared by methods described in the literature by those skilled in the art, as the following examples illustrate: Reaction of a suitable thiol with KHF₂ in

Soc., Perkin Trans. 1(11):1378 (Eng.) (1978)). Oxidation of a suitable thiol with chlorine in water with ferric chloride (FeCl_3) added gives the desired sulfonyl chloride (G. Pala, Ed. Sci. 13:461 (1958); W.J. Close, J. Amer. Chem. Soc. 82:1132 (1960)). Reaction of the heteroaromatic compound with fuming sulfuric acid gives a heteroaromatic sulfonic acid followed by treatment with phosphorous-oxychloride (POCl_3) and phosphorous chloride (PCl_5) gives the desired sulfonyl chloride (V. Georgian, R.J. Harrison, L.L. Skaletzky, J. Org. Chem. 27:4571 (1962)). Reaction of a heteroaromatic compound with manganese dioxide (MnO_2) and sodium sulfite (Na_2SO_3) in water gives the desired sulfonic acid followed by treatment with POCl_3 and PCl_5 gives the desired sulfonyl chloride (N.A. Androva, Izvest. 455 (1972); J.O. Morley, J. Chem. Comm. 88 (1976)). Treatment of the appropriate heteroaromatic chloride with sodium sulfate and HCl in water gives the desired sulfonic acid followed by treatment with POCl_3 and PCl_5 gives the desired sulfonyl chloride (T.R. Norton, J. Amer. Chem. Soc. 68:1330 (1946)). Treatment of the appropriate hydroxy compound with N,N-dimethylthiocarbonyl chloride (M.S. Newman, F.W. Hetzel, Org. Synth. Coll. Vol. IV:824 (1988); M.S. Newman, H.A. Karnes, J. Org. Chem. 31:3980 (1966)) followed by treatment of the resulting thiol, as described above, gives the desired sulfonyl chloride. Treatment of the appropriately protected thio-heteroaromatic compound with chlorine in acetic acid gives the desired sulfonyl chloride (Can. J. Chem. 55:421 (1977)). Using the literature procedures described above, the heteroaromatic sulfonyl chlorides of the present invention are prepared.

Reduction of the compound of formula AA-2 with a metal hydride (sodium borohydride, lithium

35

Oxidation of the compound of formula AA-3 (Swern oxidation) affords the aldehyde of formula AA-4 which is treated with trimethylsilylcyanide to yield the trimethylsilyl protected cyanohydrin of formula AA-5. Alternatively, the compound of formula AA-2 is
5 treated with trimethyl aluminum followed by N-methyl-O-methyl hydroxyl amine to yield the amide of formula AA-6 which is treated with lithium aluminum hydride to yield the aldehyde of formula AA-4. The trimethylsilyl cyanohydrin of formula AA-5 is reacted with a strong base (e.g. n-butyl lithium) followed by the addition of chiral epoxide of formula AA-7 (also BB-12; the synthesis of which is described in Chart
10 BB) to yield the compound of formula AA-8. The compound of formula AA-8 is dissolved in methylene chloride and cooled to -78°C and TiCl_4 is added followed by a tertiary amine base. To that solution is added trimethylorthoformate followed by additional TiCl_4 which yields the compound of formula AA-9. Treatment of the compound of formula AA-9 with base followed by trimethylsilyl chloride, then
15 treatment with an oxidizing agent (ozone), followed by treatment with tetrabutyl ammonium fluoride and then either potassium tert. butoxide or sodium hydride in an ether solvent, then affords the compound of formula AA-10. Hydrogenation of the compound of formula AA-10 then affords the compound of formula AA-11. Finally, treatment of the compound of formula AA-11 with a sulfonyl chloride of formula D-7

CHART BB

Chart BB describes the asymmetric synthesis of epoxides of formula BB-7

Catalytic Sharpless epoxidation using commercially available (+) diethyl L-tartrate provides the epoxy alcohol of formula BB-8 (see: (a) Pfenniger, A.; Synthesis 1986, 89. (b) Johnson, R.A.; Sharpless, K.B. In Catalytic
35 Asymmetric Synthesis; Ojima, I., Ed.; VCH: New York, 1993; Chapter 4.1, 103.). Alkylation of the compound of formula BB-8 with benzyl bromide (see: Lipshutz,

B.H. et al.; Synthesis 1992, 191) gives the compound of formula BB-9. Reaction of the compound of formula BB-9 with commercially available ethylmagnesium bromide affords the tertiary alcohol of formula BB-10 (see: Hanson, R.M. Chem. Rev. 1991, 91, 437). Catalytic hydrogenolysis of the compound of formula BB-10 provides the diol of formula BB-11. The compound of formula BB-11 is converted to the chiral epoxide of formula BB-12 by standard methodology (for a discussion of the conversion of vicinal diols to epoxides see: Mitsunobu, O. In Comprehensive Organic Synthesis; Trost, B.M. Ed.; Pergamon Press: Oxford, 1991; Vol. 6; Chapter 1.1, 1).

In an analogous manner, the epoxide of formula BB-7 is ultimately derived from the epoxy alcohol of formula BB-3, which in turn is prepared by Sharpless epoxidation of allylic alcohol BB-2 using commercially available (-) diethyl D-tartrate.

Alternatively, reaction of the epoxy alcohol of formula BB-8 with commercially available 4-toluenesulfonyl chloride under standard conditions affords the tosylate of formula BB-13. Reaction of the compound of the formula BB-13 with ethylmagnesium bromide under conditions similar to those described for the nucleophilic opening of arenesulfonate derivatives of glycidol (see: Klunder, J.M; Onami, T.; Sharpless, K.B. J. Org. Chem. 1989, 54, 1295) affords a mixture of the desired epoxide of formula BB-12 and hydroxytosylate of formula BB-14. The compound of formula HH-2 wherein R is *t*-Bu may also be prepared from HH-1 in two steps. First, the oxazolidinone group is cleaved by treatment of the compound of formula HH-1 with lithium hydroxide and hydrogen peroxide at 0 °C in tetrahydrofuran and water. Next, the acid intermediate is treated with N,N-dimethylformamide *t*-butylacetal in refluxing benzene to produce the ester of formula HH-2 (R is *t*-Bu). The ester of formula HH-2 wherein R is Me is prepared by heating a mixture of titanium tetrachloride and HH-1 in methanol. The compound of formula HH-3 is prepared by treatment of the ester of formula HH-2 with lithium diisopropylamide or sodium hexamethyldisilylazide to form an enolate, which is then trapped by ethyl formate to give the compound of formula HH-3. Treatment of this intermediate with tosyl chloride in 1,2-dimethoxyethane gives the compound of formula HH-4, which is then converted to the sulfur derivative of formula HH-5 by treatment with a mixture of potassium hydride and thiophenol in tetrahydrofuran. The compound of formula HH-5 is then deprotonated using *t*-butyllithium in tetrahydrofuran at low temperature. The compound of formula LLL-13, in an organic solvent such as THF or methylene chloride, is treated with a base followed by the addition of trimethylsilyl chloride. The solvent is removed from

30 the aforementioned reaction and the resulting protected tertiary alcohol is oxidized (e.g. Ru cat./t-BuOH (see Murahashi et. al. 25 chloroform to afford the compound of formula NNN-4. Alternatively, the above reaction mixture may be washed with 1 N hydrochloric acid solution during the workup instead of ammonium chloride solution to generate the compound of formula NNN-4. The amine is then converted to the derivative of formula NNN-5 by heating a mixture of the compound of formula NNN-4, 2.2 equivalents of benzyl bromide and
30 2.2 equivalents of sodium carbonate in acetonitrile. The intermediate of formula NNN-5 is then treated with 2 equivalents of lithium diisopropylamide in tetrahydrofuran to form the lithium enolate, which is trapped with acetyl chloride to afford the β -ketoamide of formula NNN-6. A solution of this amide in methylene chloride at low temperature may be treated with 1 equivalent of titanium
35 tetrachloride and 1 equivalent of diisopropylethylamine, followed by 4-heptanone to generate the compound of formula NNN-7. Conversion of the amide of formula

subsequent reaction with trialkyl aluminums or Grignard reagents in the presence of cuprous bromide-dimethylsulfide complexes provides compounds of formula QQQ-3. The individual stereoisomers are separated by HPLC using a chiral stationary phase to give the four possible stereoisomers of formula QQQ-4, QQQ-5, QQQ-6, and QQQ-7. Transfer hydrogenation of each stereoisomer with Pd/C and ammonium formate gives the amines of formula QQQ-8, QQQ-9, QQQ-10, and QQQ-11. Treatment of the amines with sulfonyl chlorides of general formula QQQ-12 and pyridine in methylene chloride provides compounds of general formula QQQ-13, QQQ-14, QQQ-15, and QQQ-16, wherein R₂ is, e.g., 5-cyano-2-pyridinyl, 1-methyl-4-imidazolyl, or 5-amino-2-pyridinyl.

CHART RRR

The procedure for the preparation of compounds of formula RRR-11 to RRR-15 is described in Chart RRR. The pyrone RRR-A is coupled to the Cbz protected benzaldehyde RRR-B in THF with AlCl₃ followed by treatment of the resulting intermediate with R₁MgX where X = Br or Cl in THF with added CuBr.Me₂S to give RRR-1. De-protection of the resulting intermediate with 10% Pd/C in methanol with added ammonium formate gives RRR-2. Separation of the racemic compound RRR-1 into its 4 enantiomers gives RRR-3 to RRR-6. De-protection of the resulting intermediates with 10% Pd/C in methanol with added ammonium formate gives the free amines RRR-7 to RRR-10. Treatment of the amines RRR-7 to RRR-10 and RRR-2 with an appropriate sulfonyl chloride gives the sulfonamides RRR-11 to RRR-14 and RRR-15, respectively.

CHART SSS

The procedure for the preparation of compounds of formula SSS-7 to SSS-9 is described in Chart SSS. The pyrone SSS-A is coupled to the Cbz protected benzaldehyde SSS-B in THF with AlCl₃ followed by treatment of the resulting intermediate with R₁MgX where X = Br or Cl in THF with added CuBr.Me₂S to give SSS-1. De-protection of the resulting intermediate with 10% Pd/C in methanol with added ammonium formate gives SSS-2. Separation of the racemic compound SSS-1 into its 2 enantiomers gives SSS-3 to SSS-4. De-protection of the resulting intermediates with 10% Pd/C in methanol with added ammonium formate gives the free amines SSS-5 to SSS-6. Treatment of the amine with an appropriate sulfonyl chloride gives the sulfonamides SSS-7 to SSS-9.

CHART TTT

benzaldehyde TTT-B in THF with AlCl_3 followed by treatment of the resulting intermediate with R_1MgX where $\text{X} = \text{Br}$ or Cl in THF with added $\text{CuBr} \cdot \text{Me}_2\text{S}$ to give TTT-1. Separation of the racemic compound TTT-1 into its 2 enantiomers gives TTT-2 and TTT-3. De-protection of the resulting intermediates with 10% Pd/C in methanol with added ammonium formate gives the free amines TTT-4 and TTT-5. Treatment of the amine with an appropriate sulfonyl chloride gives the sulfonamides TTT-6 and TTT-7.

CHART UUU

Reaction between commercially available thiourea in hot ethanol with commercially available 2-chloro-5-nitropyridine of formula UUU-1 affords the isothioureia compound of formula UUU-2. Treatment of the compound of formula UUU-2 with aqueous sodium carbonate and sodium hydroxide provides the thiol compound of formula UUU-3. Oxidation of the compound of formula UUU-3 with chlorine gas provides the sulfonyl chloride compound of formula UUU-4. Treatment of the compound of formula D-5 (e.g., the compound of formula T-4 wherein R_1 is 2-phenylethyl, R_2 is propyl, R_3 is *tert*-butyl) in dichloromethane with two equivalents of pyridine followed by one equivalent of the compound of formula UUU-4 gives the sulfonamide compound of formula UUU-5 (wherein R_1 is 2-phenylethyl, R_2 is propyl, R_3 is *tert*-butyl). Reduction of the compound of formula UUU-5 with palladium on carbon and ammonium formate affords the compound of formula UUU-6, which is the compound: 5-amino-N-[3-(1-[5,6-dihydro-4-hydroxy-2-oxo-6-(2-phenylethyl)-6-propyl-2H-pyran-3-yl]-2,2-dimethylpropyl)phenyl]-2-pyridinesulfonamide (Formula UUU-6: R_1 is 2-phenylethyl, R_2 is propyl, R_3 is *tert*-butyl).

CHART VVV

The compound of Formula VVV-1, which is 2-mercapto-5-carbamoylpyridine, is prepared via published procedure (J. Chem. Soc. 1948, 1939-1945). Treatment of a suspension of this compound in dilute hydrochloric acid with chlorine gas at 0° provides the sulfonyl chloride of Formula VVV-2.

CHART WWW

Amines of the generic formula WWW-1 are reacted with benzyl chloroformate to provide CBZ derivatives WWW-2. The individual stereoisomers of formula WWW-2 are generally separated by chiral HPLC methods, and then converted back to the free amines WWW-3 *via* hydrogenolysis. Sulfonation of the amines in the usual manner known to one of ordinary skill in the art provides the final compounds of formula WWW-4, in stereochemically pure form.

CHART XXX

Dihydropyrone XXX-1, which is prepared by procedures analogous to those in described in Preparations 17 and 84, is condensed with *meta*-nitrobenzaldehyde in the presence of aluminum trichloride to provide the benzylidene intermediate XXX-2. Conjugate reduction of the double bond using sodium cyanoborohydride, followed by
5 reduction of the nitro group *via* catalytic hydrogenation, affords amine of formula XXX-4, which is converted to the sulfonamides XXX-5 by treatment with the appropriate sulfonyl chloride in dichloromethane and pyridine.

CHART YYY

Dihydropyrones of Formula YYY-1, wherein R₁ and R₂ are propyl or
10 phenethyl, and which are synthesized as described in Preparation 84, are condensed with the aldehyde of Formula B-2 using aluminum trichloride to provide the benzylidene intermediates of formula YYY-2. Conjugate addition of *tert*-butylmagnesium chloride in the presence of copper (I) bromide-dimethyl sulfide provides compounds of Formula YYY-3. Hydrogenolytic deprotection affords amines
15 of formula YYY-4, which are converted to the sulfonamides of formula YYY-5 using the appropriate sulfonyl chloride in dichloromethane with added pyridine. The procedures used are analogous to those described for Chart D.

CHART ZZZ

Polymeric *meta*-aminobenzaldehyde is protected by treating with benzyl
20 bromide and potassium carbonate in acetonitrile at reflux to yield the compound of formula ZZZ-2. A vinyl anion is generated from 2-bromovinyltrimethylsilane of formula ZZZ-3 by treatment with *t*-butyl lithium at -78°C to -20°C. The vinyl anion so generated is cooled to -78°C and the diprotected *meta*-aminobenzaldehyde of formula ZZZ-2 is added to afford the desired allylic alcohol of formula ZZZ-3. The
25 alcohol is easily converted to the acetate or carbonate of formula ZZZ-5 by standard means (e.g., CH₃COCl, pyridine, CH₂Cl₂, 0°C). These substrates participate in palladium catalyzed allylic substitutions as delineated in Charts AAAA-CCCC (C.G. Frost; J. Howarth; J.M.J. Williams, *Tetrahedron: Asymmetry* (1992) 3:1089-1122).

CHART AAAA

30 The sodium salt of methyl acetoacetate of formula AAAA-1 generated by treating methyl acetoacetate with sodium hydride at 0°C in either DMF or THF acts as the nucleophile in a palladium catalyzed allylic substitution. If this reaction is run in the presence of palladium allyl chloride dimer of formula AAAA-3 as the palladium source and a chiral phosphine ligand (P. von Matt; A. Pfaltz, *Angew. Chem. Int. Ed. Engl.* (1993) 32:566-568), a kinetic resolution of the starting allylic
35 acetate or carbonate results in the synthesis of optically enriched allylated product

of formula AAAA-4. If the reaction with nucleophile is slow, the acetate generated from formation of the *pi*-allyl palladium intermediate isomerizes the two possible diastereomeric *pi*-allyl complexes so that a stereoselective synthesis of the allylated product occurs (B.M. Trost; P.E.J. Strege, Am. Chem. Soc. (1977) 99:1649). Treatment of the resulting vinyl silane of formula AAAA-4 with *para*-toluenesulfonic acid in acetonitrile at reflux affords the desilylated olefin of formula AAAA-5. The dihydropyrone product of formula AAAA-7 is formed by generating the dianion of the β -ketoester under standard conditions (J.R. Peterson; T.J. Winger; C.P. Miller, Syn. Comm. (1988) 18(9):949-963), (NaH, *n*-butyllithium, THF) and quenching with an appropriate symmetrical ketone of formula AAAA-6 (such as 4-heptanone). Hydrolysis of the ester (0.1 N NaOH/THF) and acidic work-up provide the dihydropyrone product of formula AAAA-7. Standard hydrogenation conditions reduce the olefin and deprotect the amine. Subsequent treatment of the amino compound with the appropriate sulfonyl chloride of formula AAAA-8 (pyridine, CH₂Cl₂) provides the desired sulfonamide protease inhibitor of formula AAAA-9.

CHART BBBB

Alternatively, the palladium catalyzed allylic substitution may be performed with the sodium anion of the requisite dihydropyrone J.R. (Peterson; T.J. Winger; C.P. Miller, Syn. Comm. (1988) 18(9):949-963) of formula BBBB-1 (dihydropyrone, NaH, THF or DMF, 0°C) as the nucleophilic partner. Once again, if palladium allyl chloride dimer of formula BBBB-3 and a chiral phosphine ligand (P. von Matt; A. Pfaltz, Angew. Chem. Int. Ed. Engl. (1993) 32:566-568) are employed as catalyst, a kinetic resolution results in the synthesis of optically pure allylated dihydropyrone of formula BBBB-4; and a stereoselective synthesis of the allylated product will occur if the reaction with nucleophile is slow relative to isomerization of the two possible diastereomeric *pi*-allyl complexes by acetate generated from formation of the *pi*-allyl palladium intermediate. Subsequent, desilylation (*p*-TsOH, CH₃CN), olefin reduction and amine deprotection (H₂/Pd/C), and sulfonylation of the amine (ArSO₂Cl, pyridine, CH₂Cl₂) with a compound of the formula BBBB-5 provides the desired dihydropyrone protease inhibitor of formula BBBB-6.

CHART CCCC

Treatment of *m*-bis(benzyl)aminobenzoic acid of formula CCCC-1 with oxalyl chloride to form the acid chloride and reaction with bis(trimethylsilyl)acetylene and AlCl₃ in methylene chloride affords the propargylic ketone of formula CCCC-2. Asymmetric reduction of the ketone with a chiral borane (H.C. Brown; Beeraraghavan Ramachandran, P. Acc. Chem. Res. (1992) 25:16-24) such as DIP chloride [(+) or (-)-

β -chlorodiisopinocampheylborane] and acetylene reduction with REDAL provides the allylic alcohol of formula CCCC-3, primarily as a single enantiomer. Formation of the carbonate of formula CCCC-4 (methyl chloroformate, pyridine, CH_2Cl_2 , 0°C) and subjection to palladium catalyzed allylic substitution with the desired dihydropyrone of formula CCCC-5 as nucleophile affords primarily one enantiomer of the allylated dihydropyrone of formula CCCC-6 (retention of configuration) (T. Hayashi; T. Hagihara; M. Konishi; M.J. Kumada, Am. Chem. Soc. (1983) 105:7768-7770). This product is transformed into the desired protease inhibitor of formula CCCC-7 as previously described in Chart BBBB.

CHART DDDD

The known cycloalkylpyranones of formula DDDD-1 are prepared by acylation of the trimethylsilyl enol ether of the corresponding cycloalkyl ketone with malonyl dichloride as described in R. Effenberger, T. Ziegler, K.-H. Schonwalder, T. Kesmarszky, B. Bauer Chem. Ber. 119: 3394-3404 (1986). Catalytic hydrogenation of the cycloalkylpyranones of formula DDDD-1 with platinum oxide (PtO_2) in acetic acid produces the cycloalkyldihydropyrones of Formula DDDD-2. The intermediate of formula DDDD-3 is then formed by aluminum chloride (AlCl_3) catalyzed condensation of the compound of formula DDDD-2 with 3-nitrobenzaldehyde, which is commercially available. Subsequent reaction of the intermediate of formula DDDD-3 with trialkyl aluminums in the presence of copper bromide-dimethyl sulfide complex ($\text{CuBr}\cdot\text{Me}_2\text{S}$) or zinc reagents generated from zinc metal, alkyl halide, cuprous cyanide (CuCN) and lithium chloride (LiCl) provides compounds of formula DDDD-4 which contain a C-3 α branched substituent. Catalytic hydrogenation of compounds of the formula DDDD-4 with Pd/C in ethanol (EtOH) provides the amine derivatives of the formula DDDD-5. Treatment of the compounds of formula DDDD-5 with sulfonyl chlorides of formula DDDD-6 and pyridine in methylene chloride (CH_2Cl_2) provides compounds of the formula DDDD-7 (e.g., wherein n is 1, 2, or 3; R_1 is ethyl or *t*-butyl; R_2 is 4-cyanophenyl or 5-cyano-2-pyridyl).

Procedures by which the compounds of the present invention are prepared are also described in International application, PCT/US93/10645, filed 9 November 1993 (WO 94/11361, published 26 May 1994), and International application, PCT/US94/00938, filed 3 February 1994 (WO 94/18188, published 18 August 1994), both of which are incorporated by reference herein.

As is apparent to those of ordinary skill in the art, the compounds of the present invention can occur in several diastereomeric forms, depending on the configuration around the asymmetric carbon atoms. All such diastereomeric forms

are included within the scope of the present invention.

Also, the dihydropyrones of the present invention can be separated into individual stereoisomers or prepared as individual diastereomers. A diastereomeric pair can be prepared wherein C-3 α is a homogeneous center and C-6 is a mixture.

- 5 All such enantiomeric and diastereomeric forms, and mixtures thereof, are included within the scope of the present invention.

The compounds of the present invention of formula I can exist in several tautomeric forms, including the particular enol forms as depicted by formula I and IA and the keto form of formula IB. (For formulas I, IA and IB, the dashed line
10 indicates that a double bond may be present or absent.) All such tautomeric forms are included within the scope of the present invention. For compounds of the present invention which are 4-hydroxy-pyran-2-ones of formula VII, the enol form predominates. For compounds of the present invention which are 5,6-dihydro-4-hydroxy-pyran-2-ones of formula VI, a mixture of the enol and keto forms is
15 commonly expected.

Also, the compounds of the present invention of formula II can exist in several tautomeric forms of the 4-hydroxy-pyrone ring, including the particular enol forms depicted by formulas II and IIA, and the particular keto form depicted by formula IIB, and mixtures thereof. All such tautomeric forms are included within
20 the scope of the present invention.

The compounds of the present invention may be in either free form or in protected form at one or more of the remaining (not previously protected) carboxyl, amino, hydroxy, or other reactive groups. The protecting groups may be any of those known in the art. Examples of nitrogen and oxygen protecting groups are set forth
25 in T. W. Greene, Protecting Groups in Organic Synthesis, Wiley, New York, (1981); J. F. W. McOmie, ed. Protective Groups in Organic Chemistry, Plenum Press (1973); and J. Fuhrhop and G. Benzlin, Organic Synthesis, Verlag Chemie (1983). Included among the nitrogen protective groups are t-butoxycarbonyl (BOC), benzyloxycarbonyl, acetyl, allyl, phthalyl, benzyl, benzoyl, trityl and the like.

30 The present invention provides for compounds of formula I and II or pharmacologically acceptable salts and/or hydrates thereof. Pharmacologically acceptable salts refers to those salts which would be readily apparent to a manufacturing pharmaceutical chemist to be equivalent to the parent compound in properties such as formulation, stability, patient acceptance and bioavailability. Examples of salts
35 of the compounds of formula I include acidic salts, such as sodium, potassium, lysine, arginine and calcium salts, and basic salts, such as the hydrochloride salt,

wherein the R substituents in formula I contain a basic moiety. Examples of salts of the compounds of formula II include the hydrohalide salts, such as the hydrochloride and hydroiodide salts; and the sodium, potassium, calcium, lysine and arginine salts.

Also included as salts of the compounds of formulae I and II of the present invention are the bis-salts, such as the bis-arginine, bis-lysine, bis-sodium, bis-potassium and bis-calcium salts, provided that the compound contains, for example, -NHSO₂-, -SO₃H, -CONH-, -OH or COOH. The bis-sodium salt is most preferred.

The compounds of the present invention are useful for treating patients infected with human immunodeficiency virus (HIV) which results in acquired immunodeficiency syndrome (AIDS) and related diseases. For this indication, these compounds may be administered by oral, intranasal, transdermal, subcutaneous and parenteral (including intramuscular and intravenous) routes in doses of 0.1 mg to 100 mg/kg of body weight per day.

Those skilled in the art would know how to formulate the compounds of this invention into appropriate pharmaceutical dosage forms. Examples of the dosage forms include oral formulations, such as tablets or capsules, or parenteral formulations, such as sterile solutions.

When the compounds in this invention are administered orally, an effective amount is from about 0.1 mg to 100 mg per kg of body weight per day. Either solid or fluid dosage forms can be prepared for oral administration. Solid compositions, such as compressed tablets, are prepared by mixing the compounds of this invention with conventional ingredients such as talc, magnesium stearate, dicalcium phosphate, magnesium aluminum silicate, calcium sulfate, starch, lactose, acacia, methyl cellulose, or functionally similar pharmaceutical diluents and carriers. Capsules are prepared by mixing the compounds of this invention with an inert pharmaceutical diluent and placing the mixture into an appropriately sized hard gelatin capsule. Soft gelatin capsules are prepared by machine encapsulation of a slurry or solution of the compounds of this invention with an acceptable inert oil such as vegetable oil or light liquid petrolatum.

Pharmaceutically acceptable formulations of the disodium salts of the compounds of the present invention include: soft elastic capsules (SEC) containing a suspension of the salt; salt tablets; salt spray coated sucrose beads; or salt spray dried matrix with an enteric or non-enteric polymer.

Formulations of the compounds of the present invention, which present the compounds in free acid form, preferably contain the free acid in non-crystalline form. Examples of such formulations include: soft elastic capsules containing free acid

protease enzyme, in which the two monomeric units are engineered to be linked by a polypeptide stretch, the method for the determination of K_i values for inhibitors uses very low concentrations of enzyme (0.2 nM) and increased incubation times (96 hours) at room temperature to improve the sensitivity in the measurement of K_i values for very potent inhibitors. The starting inhibitor concentrations are determined based on preliminary enzyme inhibition screening results which estimate the expected potency of the inhibitor. Inhibitor concentrations are then prepared using the Biomek 1000 (Beckman) and the Quadra 96 (Tomtec). Substrate (biotinylated at the amino terminal arginine and fluorescently labeled with fluorescein at the carboxyl terminal lysine), inhibitor and the tandem enzyme are allowed to react in solution at pH 5.5 (buffers identical to those used with the native dimeric enzyme) in the dark for 96 hours. Streptavidin coated polystyrene beads are added to stop the reaction. The labeled cleavage product is separated from unreacted substrate via filtration. Residual fluorescence is quantitated with the Idexx SM2000 (Idexx) and the resulting data are analyzed using the NLLSF program.

The % inhibition values and/or K_i values of representative compounds of the present invention tested in the HIV protease screening assay and/or tandem HIV protease assay are listed in Table II below.

Several compounds of the present invention, such as N-[3-(1-[5,6-Dihydro-4-hydroxy-2-oxo-6-(2-phenethyl)-6-propyl-2H-pyran-3-yl]-2,2-dimethylpropyl)phenyl]-1-methyl-1H-imidazole-4-sulfonamide were tested in known human cell lines, such as human T-cell lines, e.g., MT4 and H9, which were infected with HIV-1_{IIIB}, and certain of these compounds were further tested in peripheral blood mononuclear cells (PBMC), which were infected with HIV-1_{JRCSF} (a clinical isolate). The compounds were found to inhibit retroviral replication.

To a suspension of 150 mg of sodium hydride (60% dispersion in mineral oil) in 4 ml of dry THF under argon atmosphere at 0 °C is added dropwise 0.38 ml of methyl acetoacetate. After 10 minutes 2.3 ml of butyllithium (1.6 M in hexanes) is added. After 10 minutes a solution of 0.48 g of the compound of formula Q-1 (prepared as described in Preparation 79 (Formula S-4, refer to Chart S)) in 3 ml of tetrahydrofuran is added. The reaction mixture is stirred for 1 hour, then partitioned between ethyl acetate and dilute aqueous hydrogen chloride. The aqueous phase is extracted with two additional portions of ethyl acetate. The organic phases are combined, washed with brine, dried over magnesium sulfate and concentrated under reduced pressure. The residue is diluted with 5 mL of methanol and the resulting solution treated with 12 mL of water followed by 3.0 ml of 1 M aqueous sodium hydroxide. After 2 hours of vigorous stirring the methanol is removed under reduced pressure. The aqueous phase is washed once with diethyl ether; the ether phase is discarded. The aqueous phase is cooled to 0 °C, then acidified with dilute aqueous hydrogen chloride. The resulting precipitate is extracted with four portions of dichloromethane. The combined dichloromethane extracts are dried over magnesium sulfate and concentrated under reduced pressure. The residue is dissolved in diethyl ether-hexane and the solution is chilled to provide to provide 0.42 g of the title compound as a pale yellow solid.

20 PREPARATION 127 2-Mercapto-4-trifluoromethylpyridine

To 1.0g of 2-chloro-4-trifluoromethylpyridine (Lancaster Chemical Co) is added 10 ml of absolute ethanol and 417mg of thiourea. The reaction mixture is heated at reflux for 4 hours and 1.25 ml of a solution of 7.44g KOH in 20 ml of water is added. The solution is heated at reflux for an additional 1 hour. The

The resulting solution is extracted three times with 100 ml of methylene chloride and the resulting aqueous solution is acidified to pH 4 by addition of glacial acetic acid. The aqueous solution is extracted three times with 100 ml of methylene chloride and the organic solution is dried over anhydrous sodium sulfate. Filtration followed by

5 NaHCO_3 followed by one wash with water. After drying the organic solution over sodium sulfate (anhydrous), the solution is filtered and evaporated to dryness to give 300mg of 2-chlorosulfonyl-4-trifluoromethylpyridine which is used directly without further purification, and stored at -78°C until ready for use.

10 EXAMPLE 300-327

Following the procedures and preparations described above and using starting materials known and available to one of ordinary skill in organic synthesis, the following additional compounds in Table 3 of the present invention are made from the compounds prepared in the following preparations:

15 PREPARATION 143 Preparative separation of N-[3-[1-[5,6-Dihydro-4-hydroxy-2-oxo-6-(2-phenethyl)-6-n-propyl-2H-pyran-3-yl]-2,2-dimethylpropyl]phenyl]-carbamic acid phenylmethyl ester, to give 4 isomers.

The title compound of Preparation 134 is separated into four constituent stereoisomers which are (in order of elution from system A) 4 isomers: Isomer 1, Isomer 2, Isomer 3, and Isomer 4 with the following approximate observed retention times 10.5, 14.9, 21.4 and 65.2 minutes respectively. System A consists of a 0.46x25 cm Chiralcel OD-H column eluting at 0.5 mL/min with 20% isopropanol and 0.1 % trifluoroacetic acid in hexane (V/V). (Chiralcel OD-H is a registered trademark of Chiral Technologies, Inc., Exton PA 19341.)

The first phase of the separation is accomplished with a 2.1x25 cm ((R,R)Whelk-O 1 column eluting with 20% (V/V) isopropanol in hexane at 12 mL/min. ((R,R)Whelk-O 1 is a registered trademark of Regis Technologies, Inc., Morton Grove, IL 60053.) The peaks eluting at approximately 35 and 41 min are, respectively, a mixture of Isomers 3 and 4 and a mixture of Isomers 1 and 2 as judged from System A, above. The two mixtures are further treated as below.

In the second phase of the separation, the mixture from above that elutes near 41 minutes is injected onto a 2.1x25 cm Chiralcel OD column (Chiral Technologies, Inc.) and eluting with 15% isopropanol and 0.05% trifluoroacetic acid in hexane (V/V) at 9.0 mL/min. The peaks that elute near 11.0 and 22.0 minutes are,

respectively, Isomer 1 and Isomer 2 as judged from System A.

In the final phase of the separation, the mixture that elutes from the (R,R)Whelk-O 1 column near 35 minutes is injected onto a 2.2x25 cm Chiralcel OD column eluting with 35% isopropanol and 0.1% trifluoroacetic acid (V/V) in hexane at 9.0 mL/min. The isomer that elutes near 9.7 minutes is Isomer 3 and the one that elutes near 16.6 minutes is Isomer 4.

In both phases of the separation of stereoisomers, fractions are pooled after assay with System A and pools are concentrated to dryness on a rotary evaporator.

ethyl) Refer to Chart WWW and RRR.

The four isomers of the product of Preparation 130A (Formula RRR-1; R_1 = ethyl) are (in order of increasing retention time on System B): (ca. 16.9 min) (Isomer 1), (ca. 28.0 min) (Isomer 2), (ca. 38.2 min) (Isomer 3) and (ca. 49.8 min) (Isomer 4).

- 5 System B consists of a 0.46x25 cm Chiralcel OD-H column (Chiral Technologies, Inc.) eluting with 25% isopropanol in hexane (V/V) at 0.5 mL/min.

In Phase one of the complete resolution repeatedly inject 55 mg samples of the product of Preparation 130A onto a 2.1x25 cm (R,R)Whelk-O 1 column (Regis Technologies, Inc.). Elute the isomers at 10 mL/min with 35% isopropanol and 0.5%

The second phase consists of a 2.1x25 cm Chiralcel OD column kept at 30°.

- 15 Inject 60 mg batches of the mixture obtained in the first phase and elute the enantiomers with 25% isopropanol and 0.05% trifluoroacetic acid (V/V) at 9 mL/min. Separately pooled and concentrated, the fractions eluting near 14.5 and 23.9 min to give Isomers 1 (Formula RRR-4 where R_1 is ethyl of Chart RRR) and 2 (formula RRR-3 where R_1 is ethyl of Chart RRR) respectively.

The enantiomers are defined by elution order from System D. HPLC System D consists of a 0.46x25 cm Chiralcel OD-H column (Chiral Technologies, Inc.) with 20% isopropanol and 0.05% trifluoroacetic acid in hexane (V/V) pumped at 0.5 mL/min. Fractions eluting near 24.6, 42.9, 66.3 and 77.4 min are pooled appropriately after assay with System D. In order of elution, the four isomers are designated Isomers 1-4, respectively.

In all cases, whenever solvent is stripped from a pool the following protocol is used: Solvent is removed from pools of fractions on a rotary evaporator with house vacuum (ca. 30 mm Hg) and a water bath set at $45 \pm 5^\circ$. If acetic acid is present in the solvent, add ca. 10 mL of toluene/L of pool before the flask goes dry. Residues are then washed into tared flasks using methylene chloride and the solvent is stripped as above. Final solvent removal is accomplished at ambient temperature, 1 mmHg pressure for 2-24 hours before weighing.

NNN-7 to the dihydropyrone of formula NNN-8 may be accomplished with either sodium hydride in tetrahydrofuran or with aqueous acid. The benzyl protecting groups may then be removed by catalytic hydrogenation using 10% palladium on carbon in ethyl acetate. The resulting amine of formula NNN-9 is converted to the
5 desired sulfonamide derivative of formula NNN-10 (W-12) by treatment with 5-trifluoromethylpyridine-2-sulfonyl chloride, prepared using the methods described in Chart O, and pyridine in dichloromethane.

CHART OOO

The compound of formula OOO-7 (NNN-8) may also be generated as
10 described in Chart OOO. The amide of formula OOO-1 (NNN-5) is treated with aqueous acid to afford the compound of formula OOO-2. The methyl ester of formula OOO-3 is formed from the compound of formula OOO-2 using catalytic acid in methanol. Treatment of the methyl ester of formula OOO-3 with lithium
15 diisopropylamide, followed by trimethylsilyl chloride gives the compound of formula OOO-4. Treatment of this intermediate with either 2-methoxy-2-methyl-1,3-dioxolane followed by hydrolysis or treatment with acetyl chloride affords the β -keto ester of formula OOO-5. This β -keto ester is converted to the compound of formula OOO-6 by treatment of either the titanium enolate (formed using 1 equivalent of titanium tetrachloride and 1 equivalent of diisopropylethylamine in methylene
20 chloride at low temperature) or the lithium dianion (formed using 2 equivalents of lithium diisopropylamide in tetrahydrofuran at low temperature) with 4-heptanone. The dihydropyrone of formula OOO-7 (NNN-8) is formed by treatment of the compound of formula OOO-6 with either sodium hydride in tetrahydrofuran or aqueous base.

CHART PPP

Reduction of the commercially available ethyl 4,4,4-trifluorobutyrate of formula PPP-1, with DiBAL-H followed by in situ alkylation with 2-phenethyl magnesium bromide or chloride produces the alcohol of formula PPP-2. Swern
oxidation of the alcohol gives the ketone of formula PPP-3. The ketone is converted
30 to the dihydropyrone of formula PPP-4 by alkylation with the dianion of methyl acetoacetate followed by saponification to the acid and lactonization with base.

CHART QQQ

The aluminum trichloride catalyzed reaction of the dihydropyrone of formula QQQ-1 (PPP-4), prepared as described in Chart PPP, with the CBZ-protected 3-
35 aminobenzaldehyde (which is available from the reaction of benzyl chloroformate with commercially available 3-aminobenzaldehyde) of formula QQQ-2 and

solution; non-crystalline spray dried matrix of the free acid with an enteric or non-enteric polymer; or a solid non-crystalline matrix of free acid in polyethyleneglycol (PEG) or Gelucire 44/14 (Gattefosse, Saint Priest, France).

Syrups are prepared by dissolving the compounds of this invention in an aqueous vehicle and adding sugar, aromatic flavoring agents and preservatives. Elixirs are prepared using a hydroalcoholic vehicle such as ethanol, suitable sweeteners such as sugar or saccharin and an aromatic flavoring agent. Suspensions are prepared with an aqueous vehicle and a suspending agent such as acacia, tragacanth, or methyl cellulose.

When the compounds of this invention are administered parenterally, they can be given by injection or by intravenous infusion. An effective amount is from about 0.1 mg to 100 mg per kg of body weight per day. Parenteral solutions are prepared by dissolving the compounds of this invention in liquid vehicle and filter sterilizing the solution before placing in a suitable sealable vial or ampule.

Parenteral suspensions are prepared in substantially the same way except a sterile suspension vehicle is used and the compounds of this invention are sterilized with ethylene oxide or suitable gas before it is suspended in the vehicle.

The exact route of administration, dose, or frequency of administration would be readily determined by those skilled in the art and is dependant on the age, weight, general physical condition, or other clinical symptoms specific to the patient to be treated.

Patients to be treated would be those individuals: 1) infected with one or more than one strain of a human immunodeficiency virus as determined by the presence of either measurable viral antibody or antigen in the serum and 2) having either an asymptomatic HIV infection or a symptomatic AIDS defining infection such as i) disseminated histoplasmosis, ii) isoporiasis, iii) bronchial and pulmonary candidiasis including pneumocystis pneumonia, iv) non-Hodgkin's lymphoma, or v) Kaposi's sarcoma and being less than sixty years old; or having an absolute CD4+ lymphocyte count of less than $500/\text{mm}^3$ in the peripheral blood. Treatment would consist of maintaining an inhibitory level of the compounds of this invention in the patient at all times and would continue until the occurrence of a second symptomatic AIDS defining infection indicates alternate therapy is needed.

The utility of representative compounds of the present invention has been demonstrated in the biological tests described below:

The HIV protease screening assay is based on fluorescently labeled substrate which can be resolved from nonlabeled cleavage product using special beads coated

with streptavidin. The substrate is biotinylated at the amino terminal arginine and fluorescently labeled with fluorescein isothiocyanate (FITC) at the carboxyl terminal lysine. This assay has been employed to detect novel, nonpeptidic inhibitors of HIV-1 protease. Substrate (20 μ l of 0.2 μ M), sample (10 μ l of desired concentraion), and enzyme (10 μ l of 0.1 μ M) are added to a 96 well pandex plate. The assay is run in 0.1 M sodium acetate buffer at pH 5.5 in the presence of 1.0 M sodium chloride and 0.05% NP-40 with incubated in the dark for one hour at room temperature. Strepavidin coated polystyrene beads (40 μ l of 0.1% (w/v)) are added and the plate is incubated in the dark for an additional half hour. The labeled cleavage product is separated from the unreacted substrate via filtration and is read on the Idexx screen machine. The data are analyzed by appropriate computer algorithms to ascertain percent inhibition values.

Determination of K_i values utilizes the same materials and equipment employed for percent inhibition studies. Two-fold serial dilutions are made for a given inhibitor from 2, 3 or 4 starting concentrations with a total of 24, 36 or 48 individual inhibitor concentrations. These dilutions are performed utilizing the BioMek robotics system. The assay consists of 10 μ L of 40 nM HIV-1 protease, 10 μ L of the various inhibitor concentrations, and 20 μ L of 200 μ M substrate (40 uL total). The reaction is allowed to proceed for 90 min at room temperature, terminated with 40 μ L of avidin beads and processed (*supra vide*). An inhibitor with a known K_i is run in parallel to verify the validity of the assay. The data is processed utilizing a computer program employing a nonlinear least square analysis of the data to generate the K_i values.

The % inhibition values and/or K_i values of representative compounds of the present invention tested in the HIV protease screening assay are listed in Table I below.

In the enzyme inhibition assay described above, the sensitivity of K_i value determination is in part limited by the ability to continue to lower the enzyme concentration for compounds with high binding affinity. To prevent de-dimerization at low enzyme concentration, a tandemly linked enzyme is prepared in which the two monomers are covalently linked by an appropriate stretch of amino acid residues. Using the latter enzyme, the sensitivity of the inhibition assay is improved since much lower enzyme concentration can be utilized, as compared to the condition using the wild-type enzyme.

Protocol for K_i value determination with tandem HIV protease: Due to the greater stability (no dedimerization) of the single chain tethered (tandem) HIV

PREPARATION 5 4-Hydroxy-10-propyl-2H-cycloocta[b]pyran-2-one (Formula A-7)

Refer to Chart A.

A 250-mL, three-necked, round-bottomed flask with a nitrogen inlet and a 125-mL pressure-equalizing addition funnel is charged with diisopropyl amine (3.6 mL) and 15 mL of tetrahydrofuran. The addition funnel is charged with 4-hydroxy-2H-cycloocta[b]pyran-2-one of formula A-6 (2.292 g) and 35 mL of tetrahydrofuran. The flask is cooled to 0 °C in an ice bath, *n*-butyllithium (16.3 mL of 1.6 M solution in hexanes) is added dropwise over 3 min, and the reaction mixture is stirred another 15 min at 0 °C. The solution of 4-hydroxy-2H-cycloocta[b]pyran-2-one in THF is added dropwise over 35 min, and the reaction mixture is stirred for another 25 min at 0 °C. Hexamethylphosphoramide (4 mL) is added in one portion, and iodopropane (1.3 mL) is added dropwise over 2 min. The reaction mixture is allowed to warm to room temperature and stirred for ca. 18 h. 30 mL of 10% HCl is added and the aqueous layer is separated. The pH of the aqueous layer is lowered from 10 to 2 with concentrated HCl, and the aqueous layer is extracted with two 50-mL portions of methylene chloride. The organic layers are combined, dried over magnesium sulfate, filtered, and concentrated to give an orange oil, which is partitioned between 100 mL of 1 N sodium hydroxide and 50 mL of ether. The aqueous layer pH is adjusted from 14 to 1 with concentrated hydrochloric acid, and is then extracted with two 50-mL portions of methylene chloride. The organic layers are then combined, dried over magnesium sulfate, and concentrated to give an orange oil, which is diluted with 100 mL of ether and washed with three 25-mL portions of 10% HCl. The organic layer is then dried over magnesium sulfate, filtered, and concentrated to give 1.829 g of orange solid. Column chromatography on 100 g of silica gel (elution with 0-10% methanol in methylene chloride) gives

(3,3,3-trifluoropropyl)-2H-pyran-3-yl]-2,2-dimethylpropyl]phenyl-carbamic acid, phenylmethylester
(Formula QQQ-3 where $R_1=t\text{-Bu}$) Refer to Chart QQQ.

The title compound of Preparation 120 (850 mg) in 25 mL of tetrahydrofuran at 0°C is treated with 750 mg of aluminum trichloride, stirred 15 min, and then 700 mg of 3-benzyloxycarbonylaminobenzaldehyde is added. The mixture is allowed to stir at room temperature for 2 h then treated with 2 g of sodium carbonate monohydrate and 0.1 mL of water, stirred for 30 min, and filtered through celite washing the filter cake with tetrahydrofuran. The filtrate is concentrated in vacuo. The resulting material is dissolved in 25 mL of tetrahydrofuran and 285 mg of cuprous bromide-dimethylsulfide complex is added and the mixture stirred for 15 min before adding 11 mL of 1 M *t*-butylmagnesium bromide in tetrahydrofuran dropwise over 15-20 min. The resulting brown mixture is stirred an additional 15 min then quenched at 0°C with 50 mL of water. The layers are separated and the aqueous layer acidified with concentrated hydrochloric acid to dissolve inorganic salts and then extracted with ethyl acetate. The combined organic layers are washed with water and brine, dried over anhydrous sodium sulfate, filtered, and concentrated in vacuo. Flash chromatography on silica gel eluting with ethyl acetate in hexane gives 1.19 g of the title compound as a white to buff colored foam.

Physical characteristics are as follows:

^1H NMR (CDCl_3): δ 7.1-7.7, 6.7, 6.5, 4.4, 1.8-2.8, 1.16.

HRMS: 609.2711.
